Appendix A -Diagnostic Test Mode Assignments......61

1. Scope—This SAE Recommended Practice describes the implementation of Enhanced Diagnostic Test Modes, which are intended to supplement the legislated Diagnostic Test Modes defined in SAE J1979. Modes are defined for access to emission related test data beyond what is included in SAE J1979, and for non-emission related data. This document describes the data byte values for diagnostic messages transmitted between diagnostic test equipment, either on-vehicle or off-vehicle, and vehicle electronic control modules. No distinction is made between test modes for emission related and non-emission related diagnostics. These messages can be used with a diagnostic serial data link such as described in SAE J1850 or ISO 9141-2.

For each test mode, this document includes a functional description of the test mode, request and report message data byte content, and an example if useful for clarification.

4. Technical Requirements

4.1 Test Mode Values—Figure 1 indicates the assignment of test mode values, and indicates the type of message and where they are defined, either in SAE J1979, this document, or by the manufacturer.

Test mode values \$00 - \$0F and \$40 - \$4F are reserved to be defined in SAE J1979, which currently only includes functionally addressed messages. Usage of shaded test mode values will be defined in this document. Appendix A indicates the test mode values currently defined by both SAE J1979 and SAE J2190.

There is a one-to-one correspondence between request messages and response messages, with bit 6 of the test mode value indicating the message type.

Test Mode Value	Message type (bit 6)	Where defined		
00 - 0F	Request	SAE J1979		
10 - 1F	(bit 6 = 0)			
20 - 2F		SAE J2190		
30 - 3F				
40 - 4F	Response to	SAE J1979		
50 - 5F	Modes \$00-\$3F (bit 6 = 1)			
60 - 6F		SAE J2190		
70 - 7F				
80 - 8F	Request	Reserved for future expansion as		
90 - 9F	(bit 6 = 0)	needed		
AO - AF		Defined by vehicle manufacturer		
B0 - BF				
C0 - CF	Response to	Reserved for future expansion as		
D0 - DF	Modes \$80-\$BF (bit 6 = 1)	needed		
E0 - EF	· · ·	Defined by vehicle manufacturer		
F0 - FF				

FIGURE 1—TEST MODE VALUES

4.2 Physical Addressing—Physical addressing is used for all diagnostic test mode messages defined in this document. Typically when using SAE J1850, this type of addressing requires that the target address of the device for which the message is intended be included in the header of the message. In ISO 9141, the addressing is typically done during initialization. Only that device being addressed will respond to the request. Each device will need to be assigned a unique address to be used for communication purposes.

4.3 Miscellaneous Requirements

- 4.3.1 MESSAGE RESPONSE TIME—The vehicle controllers should respond to a diagnostic request within 100 ms of a request. If there is no response within this time period, the tool can assume no response will be received.
- 4.3.2 AUTOMATIC RETURN TO NORMAL OPERATION—During a diagnostic procedure, the on-board controllers will often be put into an abnormal mode of operation to aid in diagnostics. Examples are to report diagnostic data periodically, to disable normal message transmission, or substitute an input or output parameter. In practice, the test procedure should return all on-board controllers to a normal mode of operation at the end of the procedure.

If a test device is disconnected from the vehicle before the on-board controllers have returned to normal operation, the controllers should automatically detect that the tool is disconnected and return to a normal mode of operation. This should be accomplished by the on-board controller looking for a diagnostic message from the test device, which should be apparent from the message header. If a diagnostic message is not received for a 5 s period of time, the on-board controller should automatically return to normal operation.

Some diagnostic procedures may require more than 5 s without a required diagnostic message. For these cases, this document specifies a "test tool present" message to be transmitted by the test device at least once every 5 s if there is no other message. On-board controllers should consider this as a diagnostic message and continue in the current mode of operation.

On-board controllers should also return to normal operation at power up or after a controller reset.

4.3.3 DIAGNOSTIC MESSAGE LENGTH—This document only defines the data bytes to be used in a diagnostic message. The actual number of data bytes in a message, referred to as "n" in the message data byte descriptions in this document, depends on the requirements of the test mode and the maximum number of bytes available in a diagnostic message. The maximum number of bytes available depends on the maximum allowable message length and the number of bytes used as a message header, error detection byte(s), or for other protocol specific purposes.

For example, the SAE J1850 data link effectively limits the total number of bytes in a message to 12. If the message strategy includes a 3 byte header, 1 byte CRC, and 1 byte in-message response, then 7 data bytes are available for SAE J2190 functionality. If the message strategy includes a 3 byte header and 1 byte CRC, then 8 data bytes are available.

If other data links are used as the diagnostic data link, such as ISO 9141, there may be other message length limitations and, therefore, different limits on the number of data bytes available for SAE J2190 functionality.

4.3.4 MESSAGE RESPONSE—All diagnostic request messages, except "Test Device Present (Mode \$3F)," should receive a response from the target module. A response is optional for the "Test Device Present" message. There are two types of response messages, specific and general. Specific response messages are uniquely paired with each request message, and repeat enough data bytes of the request message to identity the specific request. The "General Response Message (Mode \$7F)" has a single test mode value. The response message to be used for a request depends on the type of the request and whether or not the module can perform the request.

When the request is for data and the module can perform the request (positive response), only the specific form of the response can be used. The response will either be a single message, multiple messages with additional data, or periodic multiple messages with updated data values.

If the request is for action, such as a request for entering a mode of operation or command to perform a function, and the module can perform the request (positive response), either the specific response message or general response message can be used. Those requests for which either response type is a valid response have both response types indicated in this document.

If the request for either data or action cannot be performed by the module (negative response), only the general response message can be used.

Figure 2 summarizes the valid response types for different types of requests.

	Positive response	Negative response
Request for data	Specific response only	General response only
Request for action	Specific or general response allowed	General response only

FIGURE 2—VALID RESPONSE TYPES

With the General Response Message a response code is returned. Response codes can indicate a negative or positive response. Standard response codes are included in the section with the definition of the General Response Message.

5. Test Modes

5.1 Modes \$00 through \$0F—Physically Addressed SAE J1979 Messages—Modes \$00 through \$0F are reserved to be defined in SAE J1979. The data byte content of the response to an SAE J1979 request when the device is addressed physically should be identical to the data byte content of the response when the device is addressed functionally. The only device that will respond to this request is the device to which the request is directed.

The response to one of these requests will be a Mode \$40 through \$4F message.

The same PID list as specified in SAE J1979 will apply when the device is physically addressed using the same test mode value. Although SAE J1979 reserves 256 PID values to be defined in that document, SAE J1979 specifies that PID values \$21 to \$3F are reserved to be defined in this document. Possible values which may be considered to be included are:

Number of header bytes and format Use of CRC versus checksum for error detection Use of in-message response Maximum number of data bytes allowed (based on header and in-message response) Use of manufacturer specific pins in the SAE J1962 connector

5.2 Mode \$10—Initiate Diagnostic Operation

5.2.1 FUNCTIONAL DESCRIPTION—The purpose of this mode is to inform devices on the serial data link that a diagnostic tool is ready to start diagnostic procedures using the data link. The on-board devices may need to alter their normal operation in order for the diagnostic procedures to be effective. One example is that the system may need to reduce the amount of data being sent on the data link to make more time available for the diagnostic messages. Another possibility is that the system may need to degrade its normal operation in order to be able to process the diagnostic requests. Systems that rely on data from modules being diagnosed may not receive data from those modules as frequently as normal. Use of this mode could inform the receiving modules that diagnostic procedures are in progress and they should not set diagnostic trouble codes based on not receiving data at the normal frequency.

An optional "level of diagnostics" byte may be used to indicate how much the normal operation must be altered in order to accommodate the extra diagnostic procedures. These levels and their corresponding amount of change must be predefined in the module by the module manufacturer. The level of diagnostics can be changed by sending a subsequent Mode \$10 command.

5.2.2 MESSAGE DATA BYTES—(See Figure 3.)

		Data Bytes (Hex)						
	#1	#2	#n					
		Request	from Tool to Vehicle					
Request diagnostic operation	10	Level (opt.)						
	Pos (eithe	sitive Resp er of the fo	onse from Vehicle to Tool Nowing is a valid response)					
Confirm diagnostic operation	Confirm diagnostic 50 Level Operation (opt.)							
General response	7F	Optional descripti	Resp. Code - 00					

FIGURE 3—MESSAGE DATA BYTES FOR MODE \$10

5.3 Mode \$11—Request Module Reset

5.3.1 FUNCTIONAL DESCRIPTION—This mode requests the module to effectively perform a module power on reset. The response message may be sent either before or after the module is reset. The response message may also be sent by modules whenever they perform a power on reset, whether requested by this test mode or not.

An optional data byte may be included in the request to indicate different levels of reset. Examples are:

First time ever connected to vehicle First time after battery disconnect After a full normal power down / power up cycle After minor power supply interruption

5.3.2 MESSAGE DATA BYTES—(See Figure 4.)

		Data Bytes (Hex) #1 #2 #3 to #n-1 #n

	Request from Tool to Vehicle									
Request module reset	11	Level (opt.)								
	Pos (eithe	itive Resp er of the fo	onse from Vehicle to Tool llowing is a valid response)							
Confirm module reset	Confirm module reset 51 Level (opt.)									
General response 7F Optional data bytes may be included (see Mode \$7F description).				Resp. Code - 00						

FIGURE 4—MESSAGE DATA BYTES FOR MODE \$11

5.4 Mode \$12—Request Diagnostic Freeze Frame Data

5.4.1 FUNCTIONAL DESCRIPTION—The purpose of this mode is to allow access to data values which were stored during freeze frame conditions specified by the vehicle manufacturer. Data content, data format, and method of retrieval are specified by the vehicle manufacturer. Typical uses for this mode are to report data stored upon detection of a system malfunction. Multiple frames of data may be stored before and/or after the malfunction is detected. The request for information includes a frame number followed by an optional indication of the data requested.

If the optional data byte is not used, or is \$00, then all data for the requested freeze frame will be reported. If the optional byte is used, then the vehicle manufacturer will define the different methods used to specify which data is requested.

The on-board module will respond to this message by transmitting the requested data.

MESSAGE DATA BYTES—(See Figure 5.)									
F									
				Data Bytes (Hex)					
	#1	#2	#3	#4 to #n					
		Request	from Too	to Vehicle					
Request diagnostic freeze frame data	12	Frame No.	ne Method to request data (optional) examples are: Bequest all data (not included or 00)						
		Request by offset (1 byte)							
			Request by PID (2 bytes)						
			Reque	st by Data Packet ID					
			Reque	st starting address for data					
			DTC w	hich caused data to be stored					
Positive Response from Vehicle to Tool									
Report diagnostic freeze frame data	52	Frame No.	Data byte	Additional optional data bytes that are in response to the request may be added to fi the message up to the maximum number of available data bytes.					

FIGURE 5—MESSAGE DATA BYTES FOR MODE \$12

5.5 Mode \$13—Request Diagnostic Trouble Code Information

5.5.1 FUNCTIONAL DESCRIPTION—The purpose of this mode is to enable a diagnostic test tool to obtain stored emission and non-emission related diagnostic trouble code (DTC) information.

This mode includes the option to request DTC information by function, where function is either powertrain body, chassis, or undefined. These are the functions used in SAE J2012 to group trouble codes. The first two bits of the first nibble for requests by function are encoded using the same convention as when codes are reported:

- 00 powertrain
- 01 chassis
- 10 body
- 11 undefined

For requests by function using this test mode, the second two bits of the first nibble are 00, and the second nibble is all zeroes. This translates to the following function groups for DTC requests:

\$00 - powertrain codes\$40 - chassis codes\$80 - body codes\$C0 - undefined

In addition, this document defines \$FF as the function group to request DTC information for all functions.

This test mode can be used to either request diagnostic trouble codes, or request the number of diagnostic trouble codes. There are two ways this mode can request DTCs.

All codes can be requested by including only the test mode value in the request.

Codes can be requested by function group (Powertrain, Chassis, Body, Undefined, or All) by sending the function group followed by \$00 as data bytes 2 and 3 (\$00 00, \$40 00, \$80 00, \$C0 00, or \$FF 00). Requesting codes for all function groups by including \$FF 00 yields the same response as not including function group in the request, but may be desired by a manufacturer for consistency with other messages.

There are also two ways this mode can request the number of DTCs.

Number of codes can be requested by including the function group as data byte 2, and not including data byte 3 (\$FF as data byte 2 must be supported as a minimum to request the total number of DTC).
Number of codes can be requested by function group (Powertrain, Chassis, Body, Undefined, or All) by sending the function group followed by \$FF as data bytes 2 and 3 (\$00 FF, \$40 FF, \$80 FF, \$C0 FF, or

\$FF FF). Requesting number of codes for all function groups by including \$FF FF yields the same response as including only \$FF as data byte 2 in the request, but may be desired by a manufacturer for consistency with other messages.

The response to a Mode \$13 request for DTC will be one or more Mode \$53 messages. If no codes are stored in the module, then the module will respond with one of the following:

Mode \$53 with no additional data bytes Mode \$53 padded with \$00 00 to fill response

Diagnostic trouble codes are transmitted as two bytes. The first two bits (high order) of the first byte for each code will be zeroes to indicate a powertrain code (refer to SAE J2012 - "Recommended Format and Messages for Diagnostic Trouble Codes" for additional interpretation of this structure). The second two bits will indicate the first digit of the diagnostic code (0 through 3). The second nibble of the first byte and the entire second byte are the next three digits of the actual code reported as Binary Coded Decimal (BCD). A powertrain trouble code transmitted as \$0143 should be interpreted as P0143, as shown in Figure 6.

FIGURE 7—MESSAGE DATA BYTES FOR MODE \$13

5.6 Mode \$14—Clear Diagnostic Information

5.6.1 FUNCTIONAL DESCRIPTION—The purpose of this mode is to provide a means for the external test device to command on-board modules to clear all diagnostic information. This information includes primarily diagnostic trouble codes, but can also include freeze frame data or other on-board test results that may be stored as a result of the trouble code being set. This extra information is device dependent.

There are three ways this mode can be used. If only the test mode value is included in the request, then all diagnostic information stored in the module is to be cleared.

Diagnostic information can optionally be cleared by function (Powertrain, Chassis, or Body) by sending P0000, C0000, or B0000 as data bytes 2 and 3. These must be encoded using the same convention as when codes are reported (see description for Mode \$13). The first two bits of the first nibble are:

00 - powertrain 01 - chassis 10 - body 11 - undefined

This translates to the following values for data bytes #2 and #3:

\$00 00 - powertrain codes \$40 00 - chassis codes \$80 00 - body codes \$C0 00 - undefined

Diagnostic information can also optionally be cleared for a single trouble code by including the trouble code to clear as optional bytes in the request. The information stored with an individual trouble code would need to be clearly identified within the module and cleared at the same time.

Caution when clearing by single trouble code: This capability should not be provided and used unless consideration is given to the possible consequences of this option. If a single fault caused multiple trouble codes to be set, and a service technician found a defective component, repaired it, and cleared a single trouble code associated with that fault, then the device would still contain trouble codes that were set based on that fault. The next technician to check codes would read those codes, and if he did not know the vehicle history, he may try to repair the vehicle based only on the remaining trouble codes, which could waste time and result in replacement of good components.

Allowing use of this feature to clear emission related trouble codes should be considered very carefully to guard against improper diagnosis. Difficult interpretation can result if the system allowed clearing a single emission related trouble code. CARB required information could report that trouble codes are stored, but they would not be reported when an SAE J1979 Mode \$04 message is sent to request those codes. Freeze frame data could be stored for a given trouble code, but that code would not be reported as stored.

5.6.2 MESSAGE DATA BYTES—(See Figure 8.)

	Data Bytes (Hex)

Positive Response from Vehicle to Tool (either of the following is a valid response)										
Diagnostic information 54 repeat data bytes 2 and 3 of request, if used cleared										
General response	7F	Optional data bytes may be included (see Mode \$7F Red description).			Resp. Code - 00					

FIGURE 8-MESSAGE DATA BYTES FOR MODE \$14

5.7 Mode \$17—Request Status of Diagnostic Trouble Codes

5.7.1 FUNCTIONAL DESCRIPTION—The purpose of this mode is to provide a means to determine the status of diagnostic trouble codes.

This mode is nearly identical in operation to Mode \$13, except that only a single DTC, followed by the status of that DTC, is reported in a single response. This mode also allows a request for the status of a single DTC. The discussion of function groups and the method of reporting DTCs is identical to the description in Mode \$13.

This test mode can be used to either request status of diagnostic trouble codes, or request the number of diagnostic trouble codes with a status bit set. There are three ways this mode can request DTCs.

All codes can be requested by only including the test mode value in the request.

Codes can be requested by function group (Powertrain, Chassis, Body, Undefined, or All) by sending the function group followed by \$00 as data bytes 2 and 3 (\$00 00, \$40 00, \$80 00, \$C0 00, or \$FF 00). Requesting codes for all function groups by including \$FF 00 yields the same response as not including function group in the request, but may be desired by a manufacturer for consistency with other messages.

Status of a single trouble code can be requested by including the trouble code as data bytes 2 and 3 in the request.

There are two ways this mode can request the number of DTCs with a status bit set.

Number of codes can be requested by including the function group as data byte 2, and not including data byte 3 (\$FF as data byte 2 must be supported as a minimum to request the total number of DTC).

Number of codes can be requested by function group (Powertrain, Chassis, Body, Undefined, or All) by sending the function group fy \$FF as data bytes 2 and 3 (\$00 FF, \$40 FF, \$80 FF, \$Co FF, or \$FF FF). Requesting number of codes for all function groups by including \$FF FF yields the same response as including only \$FF as data byte 2 in the request, but may be desired by a manufacturer for consistency with other messages.

Multiple Mode \$57 response messages may be reported due to a single Mode \$17 request message, depending on the type of request and the number of diagnostic trouble codes stored in the module. Each response message will report the status of a single DTC. If no codes are stored in the module, then the module will respond with one of the following:

Mode \$57 with no additional data bytes Mode \$57 with \$00 00 for DTC and \$00 for status

FIGURE 9—MESSAGE DATA BYTES FOR MODE \$17

5.8 Mode \$18—Request Diagnostic Trouble Codes by Status

5.8.1 FUNCTIONAL DESCRIPTION—This mode is used to retrieve diagnostic trouble codes based on the status by which they have been stored. There are various conditions under which codes are generated, for example, under normal customer driving conditions versus "on demand" codes which are generated by tests performed by the service technician. Another difference is that some codes illuminate a warning lamp while other codes do not. Some codes are retained in memory for at least 40 warmup cycles while some codes are retained only for one ignition/power up cycle.

This test mode is similar in operation to Mode \$17, except that an additional data byte is inserted as data byte #2 to indicate the specific status bits of interest. Data bytes #3 and #4 in Mode \$18 requests have the same meaning as data bytes #2 and #3 in Mode \$17 requests.

There are many philosophies among the various manufacturers for storing codes. Bit definitions have been assigned to the more commonly accepted methods. Codes stored under that definition can be requested by setting the appropriate bit(s) to "1" to retrieve the set of desired codes.

Table 1 shows the interpretation of each bit of the status byte. This definition is used for both Modes \$17 and \$18. Multiple bits can be set to "1". When requesting codes using Mode \$18, codes with any of the requested status bits will be reported.

bit	status
7	Warning lamp illuminated for this code
6	Warning lamp pending for this code, not illuminate but malfunction was detected
5	Warning lamp was previously illuminated for this code, malfunction not currently detected, code not yet erased
4	Stored trouble code
3	Manufacturer specific status
2	Manufacturer specific status
1	Current code - present at time of request
0	Maturing/intermittent code - insufficient data to consider as a malfunction

TABLE 1—INTERPRETATION OF EACH BIT OF THE STATUS BYTE

Multiple Mode \$58 response messages may be reported to a single request, depending on the number of diagnostic trouble codes stored in the module. Each response message will report up to three DTCs for which at least one of the requested status bits is set. If no codes are stored in the module that meet the requested status, then the module will respond with one of the following:

Mode \$58 with Status Requested and no additional data bytes Mode \$58 with \$00 00 as data bytes 3 and 4 Mode \$58 with \$00 00 repeated to fill response

FIGURE 10—MESSAGE DATA BYTES FOR MODE \$18

5.9 Mode \$20—Return to Normal Operation

5.9.1 FUNCTIONAL DESCRIPTION—The on-board device will return to the normal mode of operation when this message is received. All normal algorithms and normal communications will be resumed. All active diagnostic modes will be terminated without sending additional request or response messages. If the module had been unlocked using security access, then the module should also be locked.

FIGURE 11—MESSAGE DATA BYTES FOR MODE \$20

5.10 Modes \$21 to \$23—Request Diagnostic Data

5.10.1 FUNCTIONAL DESCRIPTION—The purpose of these modes is to request data values, such as analog inputs and outputs, digital inputs and outputs, freeze frame data, calculated values, bit mapped fault code data, and system status information. The request for information can be by one of three methods:

Mode \$21 - Offset (1 byte) Mode \$22 - Parameter Identification (PID) value (2 bytes) Mode \$23 – Memory Address (3 bytes)

System designers have the flexibility to maintain a table including PID numbers and data values, without having consecutive PID numbers. In this case, the tool can request either by PID number or offset. A request by offset is generally an easier method for the software to retrieve data because it does not need to search for the PID in the table. Mode \$24 allows use of the PID number one time to get the offset, with successive requests by offset for better system performance.

Figure 12 is an example of a table that could be included in the system module to utilize all of these modes. The offset is the row number of the table and is not a table entry. The location of the information within this table can be calculated by multiplying the offset times the number of bytes in each row. The location in memory can then be calculated by adding the location within the table to the base location of the table in memory.

Offset	PID1	PID2	ADDR1	ADDR2	ADDR3	SCALING1	SCALING2
00	00	01	00	1B	FE		
01	00	0A	00	2C	12		
02	01	FE	00	BA	1F		
			-				
xx	04	2C	00	65	8 A		

FIGURE 12—OFFSET/PID/ADDRESS TABLE EXAMPLE

A Mode \$21 request by offset would calculate the location of the offset information in the table, find the address and scaling for that value, and return the appropriate number of bytes of information starting at that address.

A Mode \$22 request by PID would search through the table for the requested PID, find the address and scaling for that value, and return the appropriate number of bytes of information starting at that address.

A Mode \$23 request by address would ignore this table and report data starting at the address specified in the request.

FIGURE 15—MESSAGE DATA BYTES FOR MODE \$23

5.11 Mode \$24—Request Scaling and Offset / PID

5.11.1 FUNCTIONAL DESCRIPTION—The purpose of Mode \$24 is to request either scaling and PID information by specifying offset, or request scaling and offset information by specifying PID. \$FF should be included in the request for the data byte value not being specified. If both offset and Parameter ID are specified, and the parameter ID is not correct for the offset specified, unexpected data values can be returned. Operation of this mode is similar to either Mode \$21 or \$22, depending on which value was specified in the request. The response would include offset, PID, and scaling for the requested entry. Any data byte values not supported by the module would report \$FF.

Mode \$24 can also be used to determine the PID table by incrementing the offset in repeated Mode \$24 requests.

FIGURE 16—MESSAGE DATA BYTES FOR MODE \$24

SAE J2190 Issued JUN93
5.11.3 SCALING BYTE 1—High nibble (bits 7 to 4) data type
0000 - Unsigned numeric (1 to 4 bytes) 0001 - Signed numeric (1 to 4 bytes) 0010 - Bit mapped, reported without mask 0011 - Bit mapped, reported with mask 0100 - BCD (1 to 4 bytes) 0101 - State encoded 0110 - ASCII 0111 - Signed floating point (ANSI/IEEE Std 754-1985) 1000 - Packet 1001 - Formula 1010 thru 1111 - Reserved
Low nibble (bits 3 to 0) number of bytes of value
0000 - Reserved 0001 - 1 byte 0010 - 2 bytes 0011 - 3 bytes 0100 - 4 bytes 0100 - 4 bytes 0101 thru 1111 - Reserved - may be greater than 4 for non-numeric data (ASCII or bit-mapped)
The high order nibble of the first byte defines the type of information encoding which is used to represent the parameter. The low order nibble can be read directly to determine the number of bytes used to represent the parameter.
<i>5.11.3.1 Unsigned Numeric</i> —This encoding uses a common binary weighting scheme to represent a value by means of discrete incremental steps. One byte affords 256 steps; two bytes yields 65 536 steps, etc. For example, vehicle speed may be encoded with a single unsigned numeric parameter ranging from 0 to 255 km/h. This unsigned numeric value may be up to 4 bytes in length.
5.11.2.2 Signed Numeria. This appending uses a two's complement binary weighting scheme to represent a value

- 5.11.3.2 Signed Numeric—This encoding uses a two's complement binary weighting scheme to represent a value by means of discrete incremental steps. One byte affords 256 steps; two bytes yields 65,536 steps, etc. A value can be encoded with a single unsigned numeric parameter ranging from -127 to 128. This signed numeric value may be up to 4 bytes in length.
- 5.11.3.3 Bit Mapped—Bit mapped encoding uses individual bits or small groups of bits to represent status. For every bit which represents status, a corresponding mask bit is required as part of the parameter definition. The mask indicates the validity of the bit for particular applications. A bit mapped parameter may contain 2 bytes; one representing status and one containing the validity mask, or 4 bytes; the first two representing status and the second two containing validity masks. Reference J2178, Part 2 for a discussion of bit mapped data values.

- 5.11.3.4 BCD—Conventional BCD encoding is used to represent two numeric digits per byte. The upper nibble is used to represent the most significant digit (0 9), and the lower nibble the least significant digit (0 9). Up to 8 characters (4 bytes) may comprise a single parameter.
- *5.11.3.5* State Encoded—This encoding uses a common binary weighting scheme to represent up to 256 distinct states. An example is a parameter which represents the status of the ignition switch. Codes "00," "01," "02," and "03" may indicate ignition off, locked, run, and start, respectively. The representation is always limited to 1 byte.
- 5.11.3.6 ASCII—Conventional ASCII encoding is used to represent up to 128 standard characters (MSB = logic 0). An additional 128 custom characters may be represented with MSB = logic 1. Up to four ASCII characters may comprise a single parameter.
- 5.11.3.7 Signed Floating Point—Floating point encoding is used for data that needs to be represented in floating point or scientific notation. Standard IEEE formats shall be used.
- 5.11.3.8 Packet—Packets contain multiple data values, usually related, each with unique scaling. Scaling information is not included for the individual values.
- 5.11.3.9 *Formula*—Different formulas are currently being discussed to be included. The formula type and constant values used in those formulas will be specified in scaling bytes, or reported as a different test mode.
- 5.11.4 SCALING BYTE 2—This byte is only relevant for signed and unsigned numbers and for bit mapped parameters. For other parameter types, this field is "padded" with \$00. When used with signed and unsigned numbers, this byte specifies scaling by indicating the binary point location. The binary point may be moved 127 places to the right (\$FF) or 128 places to the left (\$00). The binary point is initially assumed to be to the right of the LSB without this information.

When this byte is used for bit mapped parameters that are reported without a mask, this byte indicates which bits of the PID are supported for the current application. When bit mapped data is reported with a mask, this byte is not used.

When the data type is "formula," this byte is used to indicate the formula type, where:

\$00 - \$7F are reserved for SAE to define \$80 - \$FF are reserved for the manufacturer to define

5.11.5 SCALING BYTES 3 TO N—Optional bytes to be included if multiple bytes of bit mapped data are reported. This mode is more limiting in the number of masks that can be reported than the modes that allow retrieval of the data.

5.12 Mode \$25—Stop Transmitting Requested Data

5.12.1 FUNCTIONAL DESCRIPTION—The purpose of Mode \$25 is to stop all data transmission that was started by any test mode that can request repetitive data. If only an individual data request is to be stopped, then that value can be stopped by sending a request message for the mode that requested the data with a "0" for the data rate. In practice, if a message is already in an outgoing message queue ready to be sent, this would probably not remove that message from the queue, but it would prevent additional messages from being added to the queue. Response is either Mode \$65 or general response.

FIGURE 17—MESSAGE DATA BYTES FOR MODE \$25

5.13 Mode \$26—Specify Data Rates

5.13.1 FUNCTIONAL DESCRIPTION—The purpose of Mode \$26 is to specify the setting of data rates for data to be transmitted by request messages that can request repetitive data. Those modes include "Data Rate" as a data byte in the request message. Modules will normally have default rates associated with slow, mid, and fast. The slow rate should be about one or two samples per second, the mid rate should be normal handheld scan tool rates of about four to ten samples per second, and the fast rate 20 or more samples per second. Default rates are defined within each module and should be based on the frequency of change typical for the value reported, uses for that data, and the capability of the processor.

* NOTE: A value of \$00 should cause the data to be reported as fast as possible. A value of \$FF will cause no change in the current data rate.

FIGURE 18—MESSAGE DATA BYTES FOR MODE \$26

5.14 Mode \$27—Security Access Mode

5.14.1 FUNCTIONAL DESCRIPTION—The primary purpose of this mode is to restrict unauthorized intrusion into the onboard controller. Improper programs could potentially damage the electronics or other vehicle components or risk the vehicle's compliance to emission or safety standards. This mode is intended to be used to implement the data link security measures defined in SAE J2186.

The external device will request the controller to "Unlock" itself by sending Request #1. The controller will respond by sending a "Seed" using Response #1. The external device will respond by returning a "Key" number back to the controller using Request #2. The controller would compare this "Key" to one internally stored. If the two numbers agree, then the controller will enable ("Unlock") the external device's access to specific test modes and indicate that with Mode \$67, Response #2. If upon two attempts of a Request #2 where the two keys do not compare, then the controller will insert a 10 s time delay before allowing further attempts. This time delay will also be required before responding to a Mode \$27 request #1 for each controller power-on.

If a device supports security, but is already unlocked when a Request #1 is received, that device should respond with a Response #1 message with a seed of \$00 00. A test device could use this method to determine if a device is locked by checking for a non-zero seed.

The security system will not prevent normal diagnostic or vehicle communications between external devices and the on-board controller. Proper "Unlocking" of the controller is a prerequisite to the external device's ability to perform some of the more critical functions such as reading specific memory locations within the controller, downloading information to specific locations, or downloading routines for execution by the controller. In other words, the only access to the controller permitted while in a "locked" mode is through the product specific software. This permits the product specific software to protect itself from unauthorized intrusion.

Devices that provide security should support reject messages if a secure mode is requested while the device is locked. The reject message to be returned is a general response message Mode \$7F, with a response code \$33 to indicate the product is secured.

Some devices could support multiple levels of security, either for different functions controlled by the device, or to allow different capabilities to be exercised. These additional levels of security can be accessed by using requests #3 and #4, etc. The second data byte of the request for seed should always be an odd number, and the second data byte of the message to send the key should be the next even number.

FIGURE 19—MESSAGE DATA BYTES FOR MODE \$27

5.15 Mode \$28—Disable Normal Message Transmission

5.15.1 FUNCTIONAL DESCRIPTION—The purpose of this mode is to inhibit the on-board device from transmitting normal operating data on the link, while still performing other functions normally. The device will continue to operate in whatever diagnostic mode it was operating in prior to the Mode \$28 command.

If an unsafe or undesirable vehicle operating condition would result from the lack of normal messages, then this mode could cause all nonessential messages to be inhibited. The optional manufacturer specific "level" data byte could be used to indicate which normal mode messages to disable. Defining which messages to disable is determined by the system designer to ensure safe vehicle operation. When using this test mode, some provision must be made to allow for other devices that rely on information from the silenced device so that they do not set diagnostic trouble codes due to the lack of required information.

One use for this test mode is to reduce message traffic on the data link. This would make more time available for diagnostic messages. Another use for this mode is to allow the test equipment to emulate the remote device for diagnostic purposes. In this scenario, the test device would send a Mode \$28 request to the device to be emulated. The test device would then respond to all normal communication request messages directed to that device, most likely with data intended to cause a known response by a system that uses the information in the response. The test device can then observe the actions of those systems.

FIGURE 21—MESSAGE DATA BYTES FOR MODE \$29

5.17 Mode \$2A—Request Diagnostic Data Packet(s)

5.17.1 FUNCTIONAL DESCRIPTION—The purpose of this mode is to request diagnostic data packets that contain data values, such as analog inputs and outputs, digital inputs and outputs, freeze frame data, calculated values, bit mapped fault code data, and system status information. This Mode differs from Modes \$21 through \$23 in that multiple data packets can be requested, each containing multiple data values. These data packets can either be predefined in the on-board control module or dynamically defined using Mode \$2B or \$2C.

The on-board module will respond to this message by transmitting multiple response messages specific to that device. The data packet ID Bytes in the request allow multiple Mode \$2A data packets to be requested. Data packets should be defined which include data that is commonly used together, or changes together.

Uses for these different data packets include data such as wheel speeds for an ABS system. Data can be returned quickly with a minimal length request and response. Another use for these different data packets is to return values that do not change, such as VIN and option content. These values need to be known one time only during testing. Other data bytes may contain present values of analog and discrete device I/O, device software flags and status words, and failure codes.

5.17.2 MESSAGE DATA BYTES—(See Figure 22.)

			<u> </u>	Data Bytes (Hex)

FIGURE 22—MESSAGE DATA BYTES FOR MODE \$2A

5.18 Mode \$2B—Dynamically Define Data Packet by Single Byte Offsets

5.18.1 FUNCTIONAL DESCRIPTION—This test mode can be used to dynamically define data packets that can subsequently be requested using a Mode \$2A request. This mode is a special case alternative to using multiple Mode \$2C messages, because a single request message can be used to completely define the contents of a data packet. All other methods to specify the data values to be included in data packets using Mode \$2C would also require multiple messages, therefore, special modes to build data packets by PID or memory address are not included.

If the parameter for any offset value is longer than 1 byte, then offset data bytes in the request should be filled with \$FF for each additional byte in the data value requested (see message example). This forces the data value byte locations in the response message to mirror the offset value byte locations in the request message.

FIGURE 24—DATA PACKET EXAMPLE

5.19 Mode \$2C—Dynamically Define Diagnostic Data Packet

5.19.1 FUNCTIONAL DESCRIPTION—This test mode can be used to dynamically define data packets that can subsequently be requested using a Mode \$2A request. This single test mode is an alternative to multiple modes to define data packets by offset, PID, and memory address.

This mode allows data packets to be defined in different ways, and also allows a single data packet to include data specified in different ways. Multiple messages must be sent to define a single data packet. Each message constructs a portion of the data packet, and includes an indication of how the data is being requested, the starting byte of the data packet, and the number of bytes to be specified for the data packet.

Data packets can be shortened by sending a data packet definition with the starting byte indicating the first data byte not to be included, and 0 as the length. This should be interpreted as 0 bytes at the starting location, which means that data byte is not in the response message.

Data packet definitions can be cleared by sending a message with 1 as the starting data byte and 0 as the number of bytes. Requesting this data packet would result in a response which would include the mode value, data packet ID, and no data.

Data packet definitions can be removed by sending a message with 0 as the starting data byte and 0 as the number of bytes. This would free memory space, if needed.

An optional feature of this mode is to request the present definition for the data packet. This is accomplished by sending a Mode \$2B with the data packet ID as the only additional data byte. The result is multiple \$6B responses, each including data bytes that resemble the \$2B messages that created the data packet.

5.19.2 MESSAGE DATA BYTES—(See Figure 25.)

FIGURE 26B—DATA PACKET DEFINITION EXAMPLE (CONTINUED)

5.20 Mode \$2F—Input/Output Control by PID

5.20.1 FUNCTIONAL DESCRIPTION—This capability allows the tester to verify proper operation of external input and output components and circuitry by isolation techniques. Real world sensor inputs can be temporarily bypassed, and direct control of output devices can be achieved. Since substitution may cause the control module to operate in a manner which is unsuitable or unsafe for "on-the-road" operation, precautions must be taken to ensure safe operation. The substituted value is used only for the duration of the diagnostic procedure, and when the module is returned to normal operation, or control of the data value is returned to the vehicle, then the substituted value reverts back to the normal value determined by the control system.

Parameter IDs (PIDs) are assigned by the manufacturer for those input, output, and intermediate (calculated) values that are allowed to be substituted. The PID assignments can be the same PID values that are used with a Mode \$22 request for data by PID.

5.20.2 MESSAGE DATA BYTES—(See Figure 27.)

5.21 Mode \$30—input/output Control By Data Value Id

5.21.1 FUNCTIONAL DESCRIPTION—This mode is identical in purpose and function to mode \$2f, except that the parameter to be controlled is specified by a 1 byte data value ID instead of a 2 byte PID.

Data value IDs are assigned by the manufacturer for those input, output, and intermediate (calculated) values that are allowed to be substituted.

FIGURE 28—MESSAGE DATA BYTES FOR MODE \$30

5.22 Modes \$31 to \$33—Perform Diagnostic Routine by Test Number

5.22.1 FUNCTIONAL DESCRIPTION—The purpose of these modes is to execute diagnostic tests and obtain test results. The diagnostic routines are manufacturer defined and executed in the control module by referencing the test number. Each module may support up to 255 distinct diagnostic routines. Definition of the routines is defined by the module manufacturer.

Reported results may consist of any set of return information, such as measured test values or fault codes.

Three sets of messages are used to perform tests resident in an on-board control module. These messages perform three functions:

Mode \$31 - Enter/start Diagnostic Routine by Test Number Mode \$32 - Exit/stop Diagnostic Routine by Test Number Mode \$33 - Request Diagnostic Routine Results by Test Number

The tests are known by the module and identified by a test number. They are usually permanently stored in the module, but may have been downloaded by Modes \$34 and \$36.

These test numbers could either be tests that run instead of normal operating code, or could be routines that are enabled in this mode and execute with the normal operating code. In the first case, normal system operation for the controller being tested is not possible. In the second case, multiple diagnostic routines can be enabled that run while all other parts of the system are functioning normally.

Any combination of the messages can be used, depending on the implementation in the module. Some examples are:

Tester sends a Mode \$31 message to start a test. The module reports that the test has started with a Mode \$71 and runs the test until a Mode \$32 is sent to stop the test. The module exits the test and informs the tester with a Mode \$72 that the test has stopped. The tester then requests test results with a Mode \$33, and the module reports the results with a Mode \$73 message.

Tester sends a Mode \$31 message to start a test. The Module confirms the test has started, exits when the test is done and reports results using Mode \$73.

- Tester sends a Mode \$31 message to start a test. The Module starts the test and periodically reports results using Mode \$73 until a Mode \$32 is sent to stop the test.
- The on-board controller starts a test automatically, stops the test automatically and reports results using a Mode \$73 message automatically. This requires no request messages from the tester.

These examples demonstrate both maximum and minimum use of the available message. Test equipment needs to know what tests are available, which messages are required, and how to interpret the results.

The general purpose response, Mode \$7F, may also be used instead of a Mode \$71 or Mode \$72 message to acknowledge entry or exit from a diagnostic routine.

5.23 Modes \$34 to \$37—Data Transfer

5.23.1 FUNCTIONAL DESCRIPTION—These modes allow the transfer of data either from a tester to an on-board module or from an on-board module to a tester. Modes defined are:

Mode \$34 - Request Download - tool to module

Mode \$35 - Request Upload - module to tool

Mode \$36 - Data Transfer

Mode \$37 - Request Data Transfer Exit

Download is defined as data transfer from the tool to the controller in the vehicle. Upload is defined as data transfer from the controller in the vehicle to the tool.

FIGURE 31B—MESSAGE DATA BYTES FOR MODES \$38 THROUGH 3A (CONTINUED)

5.25 Mode \$3B—Write Data Block

5.25.1 FUNCTIONAL DESCRIPTION—The purpose of this mode is to provide a means for the external test device to change the contents of a data block. The data block numbers and associated memory locations need to be known by the on-board device. This mode does not allow off-board test equipment to change any memory locations other than for those data blocks predefined in the on-board device.

The number of data bytes included in the request message for each block number depends on the system design and intent of the usage for that block.

Possible uses for this mode are:

Clear non-volatile memory Reset learned values in a single table Set option content Set Vehicle Identification Number (VIN) Change calibration values

This mode can be used to clear or reset tables stored in non-volatile memory. A data block number could be defined as memory locations that need to be either cleared or reset to predefined initial values, such as learned values in a table. Sending the data block number with no data bytes could cause the on-board system to clear/reset all learned values associated with that data block number to known nominal values.

Another use is to allow the VIN to be input. A data block number could be defined to expect a portion of the VIN. Multiple messages would be required to send the entire 17-character VIN. Whatever data values were included in the request message would be stored in the memory locations known by the on-board system for VIN.

In some systems, this mode could be used for programming calibrations or vehicle specific information in the assembly plant or service without using secured methods for reprogramming. If desired that those values not be changed after production, the capability to modify those data blocks could be disabled after the initial change.

5.25.2 MESSAGE DATA BYTES—(See Figure 32.)

FIGURE 32—MESSAGE DATA BYTES FOR MODE \$3B

5.26 Mode \$3C—Read Data Block

5.26.1 FUNCTIONAL DESCRIPTION—The purpose of this mode is to provide a means for the external test device to read the contents of a data block. The data block numbers and associated memory locations need to be known by the on-board device. This mode does not allow off-board test equipment to read any memory locations other than for those data blocks predefined in the on-board device.

The number of data bytes included in the Response for each block number depends on the system design and intent of the usage for that block.

Possible uses for this mode are to read:

Learned values in a single table Option content Vehicle Identification Number (VIN) Calibration values

FIGURE 33—MESSAGE DATA BYTES FOR MODE \$3C

5.27 Mode \$3F—Test Device Present (no operation performed)

5.27.1 FUNCTIONAL DESCRIPTION—This mode can be used to indicate a tool or test device is present. This message may be required, in the absence of other diagnostic messages, to prevent modules from automatically returning to normal operation. The presence of this message will indicate that the system should remain in a diagnostic mode of operation.

This message will normally be sent to all modules in the vehicle. Because this message is not a specific request for a controller to do something, There is no required response message to the test tool present message. However, if the message strategy includes a response to this, a general response message should be used. If the vehicle contains multiple modules, then multiple responses will be sent, using available data link time.

FIGURE 34—MESSAGE DATA BYTES FOR MODE \$3F

5.28 Mode \$7F—General Response Message

5.28.1 FUNCTIONAL DESCRIPTION—Physical requests for information must be responded to by the intended receiver of the request. This message is intended to be a generic response to any request message when data does not need to be returned to the test device. This is an alternative to a specific response when the request is for an action to be performed by the controller. This is also a reject message (negative response) for requests for data or for an action to be performed. See the "Message Response" section for a more detailed discussion about the use of this message.

The response may be an acknowledge that the message was received, or may include a code indicating the reason for rejection if a valid response is not possible. This response assumes that a valid message has been received, and is not intended to inform the sender of an invalid message or to report system failures. Valid response codes are included in this section. Response codes from \$00 to \$7F are reserved to be defined in this document, and codes from \$80 to \$FF are reserved to be defined by the vehicle manufacturer.

The format for the general response message is a \$7F for the first data byte after the header, optional data bytes that repeat data bytes of the request, and the response code. If a fixed message length is required and there are not enough data bytes in the request, the message should be padded with \$00 to fill the remaining data bytes.

5.28.2 MESSAGE DATA BYTES—(See Figure 35.)

FIGURE 36—GENERAL RESPONSE EXAMPLES

5.28.4 RESPONSE CODES—Figure 37 includes response codes and descriptions to be used with the general response messages.

Resp Code	Response Code Description
00	AFFIRMATIVE RESPONSE
	This response code is used to indicate affirmative response to a request message. It indicates that the requested action will be taken or is already complete.
10	GENERAL REJECT
	This response code is used to indicate a negative response to a request message. No reason or explanation for the rejection is given.
11	MODE NOT SUPPORTED
	This response code is used to indicate negative response to a request message. It indicates that the requested action will not be taken because the ECU does not support the requested mode.
12	SUB-FUNCTION NOT SUPPORTED or INVALID FORMAT
	This response code is used to indicate negative response to a request message. It indicates that the requested action will not be taken because the ECU does not support the arguments of the requested mode or the format of the argument bytes do not match the prescribed format for the specified mode.
21	BUSY REPEAT REQUEST
	This response code indicates that the ECU is <u>temporarily</u> too busy to perform the requested operation. In this circumstance repetition of the request will <u>eventually</u> result in an affirmative response. This code may be returned while an ECU is in the process of clearing stored codes or fetching information. Whenever completion of the requested operation will exceed the maximum response time limit, it is appropriate to use the BUSY REPEAT REQUEST message to lengthen the acceptable response period.
22	CONDITIONS NOT CORRECT or REQUEST SEQUENCE ERROR
	This response code is used to indicate negative response to a request message. It indicates that the requested action will not be taken because the ECU prerequisite conditions are not met. This request may elicit an affirmative response at another time. This code may occur when sequence sensitive requests are issued in the wrong order.
23	ROUTINE NOT COMPLETE
	This response code is used to indicate that the message was properly received and the routine is in process, but not yet completed.

FIGURE 37A—GENERAL RESPONSE CODES

Resp Code	Response Code Description
31	REQUEST OUT OF RANGE
	This response code is used to indicate negative response to a request message. It indicates that the requested action will not be taken because the ECU detects the request message contains a data byte which attempts to substitute a value beyond its range of authority (ex: attempting to substitute a data byte of 111 when the data is only defined to 100).
33	SECURITY ACCESS DENIED
	This response code is used to indicate negative response to a request message. It indicates that the requested action will not be taken because the ECU's security strategy has not been satisfied by the tester.
34	SECURITY ACCESS ALLOWED
	This response code is used to indicate positive response to a request message. It indicates that the ECU's security strategy has been satisfied by the tester.
35	INVALID KEY
	This response code is used to indicate negative response to a request message. It indicates that security access has not been given because the ECU's security key was not matched by the tester (this counts as an attempt to gain security access).
36	EXCEED NUMBER OF ATTEMPTS
	This response code is used to indicate negative response to a request message. It indicates that the requested action will not be taken because the Tester has unsuccessfully attempted to gain security access more times than the ECU's security strategy will allow.
37	REQUIRED TIME DELAY NOT EXPIRED
	This response code is used to indicate negative response to a request message. It indicates that the requested action will not be taken because the tester's latest attempt to gain security access was initiated before the ECU's required timeout period had elapsed.
40	DOWNLOAD NOT ACCEPTED
	This response code indicates that an attempt to download to an ECU's memory cannot be accomplished due to some fault condition.
41	IMPROPER DOWNLOAD TYPE
	This response code indicates that an attempt to download to an ECU's memory cannot be accomplished because the module does not support the type of download being attempted.
42	CAN'T DOWNLOAD TO SPECIFIED ADDRESS
	This response code indicates that an attempt to download to an ECU's memory cannot be accomplished because the module does not recognize the target address for the download as being available.

FIGURE 37B—GENERAL RESPONSE CODES (CONTINUED)

Resp Code	Response Code Description
43	CAN'T DOWNLOAD NUMBER OF BYTES REQUESTED
	This response code indicates that an attempt to download to an ECU's memory cannot be accomplished because the module does not recognize the number of bytes requested for the download as being available.
44	READY FOR DOWNLOAD
	This response code indicates that a download to an ECU's memory can be accomplished.
50	UPLOAD NOT ACCEPTED
	This response code indicates that an attempt to upload from an ECU's memory cannot be accomplished due to some fault condition.
51	IMPROPER UPLOAD TYPE
	This response code indicates that an attempt to upload from an ECU's memory cannot be accomplished because the module does not support the type of upload being attempted.
52	CAN'T UPLOAD FROM SPECIFIED ADDRESS
	This response code indicates that an attempt to upload from an ECU's memory cannot be accomplished because the module does not recognize the target address for the upload as being available.
53	CAN'T UPLOAD NUMBER OF BYTES REQUESTED
	This response code indicates that an attempt to upload from an ECU's memory cannot be accomplished because the module does not recognize the number of bytes requested for the upload as being available.
54	READY FOR UPLOAD
	This response code indicates that an upload from an ECU's memory can be accomplished.
61	NORMAL EXIT WITH RESULTS AVAILABLE
	This response code is used to indicate response to a request message. It indicates that the requested exit action will be taken, or is already complete, and that additional information is available in the form of data, stored codes, or PIDs.
62	NORMAL EXIT WITHOUT RESULTS AVAILABLE
	This response code is used to indicate response to a request message. It indicates that the requested exit action will be taken, or is already complete, but no additional information is available in the form of data, stored codes, or PIDs.

FIGURE 37C—GENERAL RESPONSE CODES (CONTINUED)

Resp Code	Response Code Description			
63	ABNORMAL EXIT WITH RESULTS			
	This response code is used to indicate response to an exit request message. It indicates that the requested exit action will be taken, or is already complete. It is also indicates that the requested execution did not occur in the expected manner and that additional information is available in the form of data, stored codes, or PIDs.			
64	ABNORMAL EXIT WITHOUT RESULTS			
	This response code is used to indicate response to a exit request message. It indicates that the requested exit action will be taken, or is already complete. It is also indicates that the requested execution did not occur in the expected manner, but additional information is not available.			
71	TRANSFER SUSPENDED			
	This response code indicates that a block transfer operation was halted due to some fault, but will be completed later.			
72	TRANSFER ABORTED			
	This response code indicates that a block transfer operation was halted due to some fault, and will not be completed later.			
73	BLOCK TRANSFER COMPLETE / NEXT BLOCK			
	This response code indicates that a block transfer operation has been completed successfully.			
74	ILLEGAL ADDRESS IN BLOCK TRANSFER			
	This response code indicates that the starting address included in the block transfer request message is either out of range, protected, the wrong type of memory for receiving data, or cannot be written to for some reason.			
75	ILLEGAL BYTE COUNT IN BLOCK TRANSFER			
	This response code indicates that the number of data bytes included in the block transfer request message is either more than the block transfer can accommodate, requires more memory than is available at the requested starting address, or cannot be handled by the block transfer software.			
76	ILLEGAL BLOCK TRANSFER TYPE			
	This response code is used to indicate that the block transfer type included in the request for block transfer is not valid for this application.			

FIGURE 37D—GENERAL RESPONSE CODES (CONTINUED)

Resp Code	Response Code Description	
77	BLOCK TRANSFER DATA CHECKSUM ERROR	
	This response code is used to indicate that the block transfer data checksum calculated for the block transfer message does not agree with the expected value.	
78	BLOCK TRANSFER MESSAGE CORRECTLY RECEIVED	
	This response code is used to indicate that the block transfer message was received correctly, and that any parameters included in the message were valid, but the action to be performed may not be completed yet. This response code can be used to indicate that the message was properly received and does not need to be retransmitted, but the receiving device is not yet ready to receive another block transfer.	
79	INCORRECT BYTE COUNT DURING BLOCK TRANSFER	
	This response code indicates that the number of bytes that was expected to be sent was not the same as the number of bytes received.	
80 to	MANUFACTURER SPECIFIC CODES	
	These response codes are reserved to be specified by the vehicle manufacturer.

TABLE A1—DIAGNOSTIC TEST MODE ASSIGNMENTS

Mode	Message Name	Mode	Message Name
28	Disable Normal Message Transmission	68	Confirm Normal Message Transmission Disabled
29	Enable Normal Message Transmission	69	Confirm Normal Message Transmission Enabled
2A	Request Diagnostic Data Packet(s)	6A	Report Diagnostic Data Packet(s)
2B	Define Diagnostic Data Packet by Offset	6B	Confirm Data Packet Defined by Offset
2C	Define Diagnostic Data Packet	6C	Confirm Data Packet Defined
2D		6D	
2E		6E	
2F	Input/Output Control by PID	6F	Confirm Input/Output Control by PID
30	Input/Output Control by Data Value ID	70	Confirm Input/Output Control by Data Value ID
31	Request Start Diagnostic Routine by Test No.	71	Confirm Diagnostic Routine Started by Test No.
32	Request Stop Diagnostic Routine by Test No.	72	Confirm Diagnostic Routine Stopped by Test No.
33	Request Diagnostic Routine Results by Test No.	73	Report Diagnostic Routine Results by Test No.
34	Request Download	74	Report Download Status
35	Request Upload	75	Report Upload Status
36	Transfer Data	76	Data Transfer
37	Request Stop Data Transfer	77	Confirm Data Transfer Stopped
38	Request Start Diagnostic Routine by Address	78	Confirm Diagnostic Routine Started by Address
39	Request Stop Diagnostic Routine by Address	79	Confirm Diagnostic Routine Stopped by Address
ЗA	Request Diagnostic Routine Results by Address	7A	Report Diagnostic Routine Results by Address
3B	Write Data Block	7B	Confirm Data Block Written
3C	Read Data Block	7C	Report Contents of Data Block
3D		7D	
3E		7E	
3F	Test Device Present - No Operation Performed	7F	General Response Message (accept/reject)

Rationale—Not applicable.

Relationship of SAE Standard to ISO Standard—Not applicable.

Application—This SAE Recommended Practice describes the implementation of Enhanced Diagnostic Test Modes, which are intended to supplement the legislated Diagnostic Test Modes defined in SAE J1979. Modes are defined for access to emission related test data beyond what is included in SAE J1979, and for non-emission related data. This document describes the data byte values for diagnostic messages transmitted between diagnostic test equipment, either on-vehicle or off-vehicle, and vehicle electronic control modules. No distinction is made between test modes for emission related and non-emission related diagnostics. These messages can be used with a diagnostic serial data link such as described in SAE J1850 or ISO 9141-2.

For each test mode, this document includes a functional description of the test mode, request and report message data byte content, and an example if useful for clarification.
